

Change in Oceanicity Index

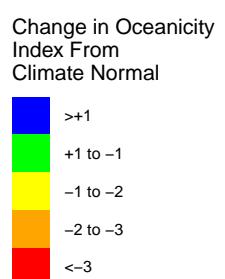

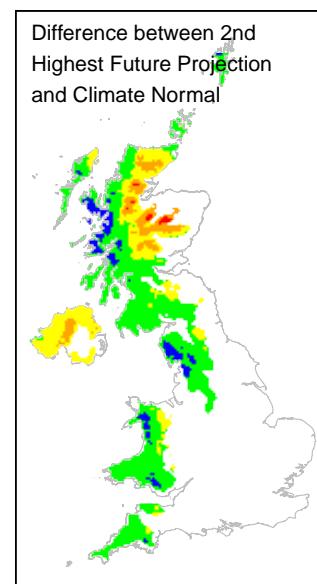

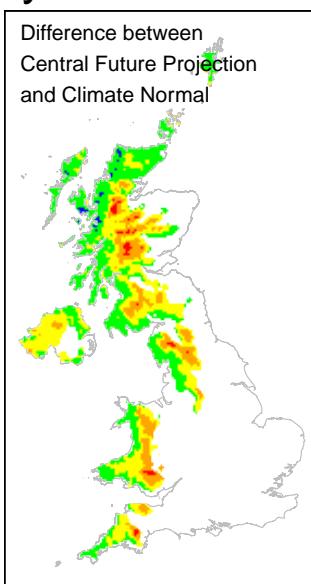

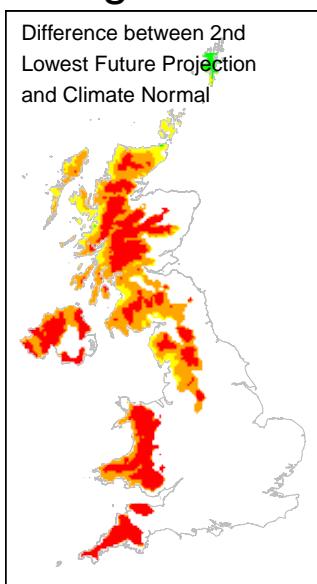

Baseline Oceanicity Index (1981 – 2000)

Future Oceanicity Index (2061 – 2080)

Change in Oceanicity Index

Rainforest zone defined as oceanicity index >15. The 2nd Lowest, Central and 2 highest projections represent the 2nd, 7th and 11th lowest ensemble members when ordered by extent of modelled rainforest zone. In this plot, the baseline climate normal is represented by the Central Projection of the 12 ensemble members (top middle). The top row shows baseline projections, middle shows future and the bottom row shows the difference between the future projections and the baseline climate normal. The change in rainforest zone maps are then as follows; bottom left = climate normal – 2nd Lowest Future Extent (middle left), bottom middle = climate normal – Central Future Extent (middle middle), bottom right = climate normal – 2nd Highest Future Extent (middle right). The change in Oceanicity maps only look at areas with an Oceanicity Climate Normal >10
